

Algebraic Cryptanalysis of AO Primitives Based on Polynomial Decomposition

Applications to RAIN and Full AIM-I/III/V

Abstract. The LowMC-based post-quantum signature scheme Picnic was selected as a third-round candidate for NIST PQC, attracting wide attention to the design of efficient and secure post-quantum signature schemes using Symmetric Techniques for Advanced Protocols (STAP). Symmetric primitives designed for advanced protocols such as secure multi-party computation (MPC), fully homomorphic encryption (FHE), and zero-knowledge (ZK) proof systems, with the goal of reducing the number of multiplication operations, are referred to as arithmetic-oriented (AO) primitives. These cryptographic primitives are typically constructed over large finite fields, which makes classical statistical analysis methods like differential and linear cryptanalysis inefficient. Due to their inherent algebraic properties, the mainstream security evaluation approaches are based on algebraic attacks. In this paper, we analyze the security of the MPC-friendly primitives RAIN (CCS 2022) and AIM (CCS 2023) used in the post-quantum signature schemes Rainier and AIMer. Existing algebraic attacks on RAIN and AIM were conducted over \mathbb{F}_2 . We propose a novel algebraic attack over \mathbb{F}_{2^n} that uses the polynomial decomposition to reduce degrees of equations. By further combining with the guess-and-determine technique, meet-in-the-middle modeling, and resultant, we are able to attack RAIN and the full AIM. Specifically, we successfully attacked 2-round RAIN with $2^{73.7}/2^{107.0}/2^{138.9}$ primitive calls, 3-round RAIN with $2^{160.6}/2^{236.0}/2^{311.1}$ primitive calls, for the 128/192/256-bit key. For the full AIM, we successfully attacked it with $2^{114.0}/2^{163.2}/2^{228.3}$ primitive calls for the 128/192/256-bit key. The attack complexities mainly lie in solving univariate polynomial equations and computing resultants, and hence the complexity evaluations are accurate.

Keywords: Polynomial Decomposition · MITM · RAIN · AIM · Guess-and-determine · Resultant.

1 Introduction

The emergence of privacy-preserving protocols such as zero-knowledge (ZK) proofs, secure multi-party computation (MPC), and fully homomorphic encryp-

tion (FHE) has gained extensive attention and wide research in recent years. These advanced schemes have motivated the development of one type of novel symmetric cryptographic primitives known as *arithmetic-oriented* (AO) primitives. AO primitives are designed to optimize performance in arithmetic circuits, with main focus on minimizing the number of multiplication operations [25]. Different from classical symmetric ciphers like AES [35] and SHA-3 [19] that are designed for optimizing speeds in software or hardware, the algebraic structures of these primitives are designed to be well aligned with the privacy-preserving protocols that operate over large finite fields. For instance, the AO primitives Rescue variants [4,38,8], POSEIDON variants [24,25], Arion [36], GRIFFIN [21], Reinforced Concrete [22], Tip5 variants [39], and the Monolith family [23] are all operating over large prime fields. MiMC [1], Jarvis [6], Vision [4], RAIN [18] and AIM [30] etc. are working on binary extension fields with large degrees of extension. GMiMC [3], Ciminion [17], Anemoi [14] are operating over both large prime fields and binary extension fields.

In parallel, the urgency to develop post-quantum digital signatures has intensified and the MPC-in-the-Head (MPCitH) paradigm proposed by Ishai et al [26] presents a novel constructing way. The MPCitH paradigm is basically a non-interactive zero-knowledge proof of knowledge (NIZKPoK) that verifies the correspondence between the input (the secret key of a signature) and the output (the public key of the signature) of a specific one-way function. The performance of MPCitH-based signatures is typically closely related to the number of non-linear operations in the circuit of the underlying one-way function. Therefore, AO primitives that target to reduce the number of multiplication operations are well-suited to meet this requirement. The authors in [15,28] pioneered the research of NIZKPoK-based signatures and designed the Picnic scheme, which utilized the MPC-friendly block cipher LowMC to instantiated a one-way function. In this paper, we mainly study the MPC-friendly one-way functions RAIN [18] and AIM [30]. Their MPCitH-based signatures Rainier and AIMer (a candidate of NIST Round 1 PQC Additional Signatures¹ and a final algorithm of Korean Round 2 PQC Competition²) managed to reduce multiplications as well as the signature sizes.

Security of AO primitives. The cryptanalysis of AO cryptographic primitives has experienced significant advances in recent years. The security of an AO primitive often relies on the hardness of solving an equation system using a single plaintext-ciphertext pair since very few amount of available plaintext-ciphertext data can be obtained. Besides, due to the inherent algebraic properties of AO primitives, algebraic attacks typically outperform other statistical analysis such as differential and linear cryptanalysis. For instance, Gröbner basis attacks combined with low-degree equation modeling on some AO primitives are proposed in [12,2,32]. In Crypto 2024 and Asiacrypt 2024, two novel algebraic attacks have

¹ <https://csrc.nist.gov/Projects/pqc-dig-sig/round-1-additional-signatures>

² <https://kpqc.or.kr>

been proposed, named the FreeLunch [11] and the resultant-based method [40], both of which have proved high efficiency for a wide range of AO primitives.

Another type of widely used attacks is the guessing-based algebraic attack [34,9,10,37,41]. For RAIN and AIM, Zhang et al. proposed guess-and-determine attacks on 2-round RAIN and full AIM-III (the variant targeting for 192 bits of security) at ASIACRYPT 2023 [41]. They linearize the S-box by guessing the power of the input of the S-box such that the attack is reduced to solve a system of linear equations. At FSE 2024 [33], Liu et al. further improved the attack on 2-round RAIN by using Dinur’s methods [16] or the Crossbred method [27] to solve the low-degree equivalent equation representation of RAIN. They also employed the fast exhaustive search method [13] to solve the low-degree equivalent equation of AIM, demonstrating that AIM does not meet its security claims. In CCS 2023 [30], the designers of AIM proposed using Gröbner basis attacks and XL attacks to analyze the security of 3-round RAIN. They estimated the complexities of the XL attacks based on the strong independence assumption between the equations with $\omega = 2$, where ω denotes the exponent of the time complexity of matrix multiplication. The authors also admit that the independent assumption is too ideal, therefore, the complexities in [30] do not imply that RAIN has been broken. At ASIACRYPT 2024 [32], Liu et al. improved the equation modeling in [30] and constructed more equations to build the over-determined system for 3-round RAIN and reduced the time complexities of the Gröbner basis attacks. It is worth noting that the aforementioned attacks on RAIN and AIM are implemented over \mathbb{F}_2 , which will introduce a large number of variables and enlarge the scale of the equation system. Besides, only one pair of plaintext and ciphertext is available for attacks on keyed AO primitives, which makes the construction of an over-determined system and linearization technique over \mathbb{F}_2 difficult. Furthermore, algebraic attacks that directly solve equations using Gröbner basis on AO primitives over \mathbb{F}_2 fail to make full use of the inherent algebraic properties of the AO primitives, and the complexities of Gröbner basis algorithms are not precise, leading to inaccurate evaluation of the security of AO primitives. In this paper, we propose a novel algebraic attack over the extension field \mathbb{F}_{2^n} that can make full use of the properties of linear layers. Such an attack can derive more powerful attacking results and the evaluation of complexities are accurate.

Our Contributions. In this paper, we propose to use polynomial decomposition in algebraic attacks on RAIN and AIM over \mathbb{F}_{2^n} . Our attack is highly flexible, allowing integration with guess-and-determine attacks [41] and resultant-substitution [40] methods. The complexity of our attack is primarily from solving univariate polynomial equations and computing a bivariate resultant, which can be estimated accurately. Our main contributions are as below and Table 1 presents the comparison of our attacks with existing ones.

1. We discovered a useful property of linearized polynomials: a linearized polynomial \mathcal{L} of degree 2^{n-1} can be decomposed into $\mathcal{L} = \mathcal{L}_1(\mathcal{L}_2^{-1})$ with $\deg(\mathcal{L}_1) \leq 2^{\lceil n/2 \rceil}$ and $\deg(\mathcal{L}_2) \leq 2^{\lceil n/2 \rceil}$. This property cannot be utilized in algebraic

attacks over \mathbb{F}_2 , but can be exploited in algebraic attacks over \mathbb{F}_{2^n} . Taking advantage of this property and combining with the meet-in-the-middle (MITM) modeling, we decompose the linearized polynomial and derive a univariate polynomial equation with a degree not exceeding $2^{n/2+2}$ for 2-round RAIN ($n \in \{128, 192, 256\}$). Solving this relatively low-degree univariate polynomial equation can significantly reduce the attack complexity. The 2-round RAIN can be broken with $2^{73.7}/2^{107.0}/2^{138.9}$ primitive calls for 128/192/256-bit key, respectively.

2. To extend our algebraic attack to the full-round (3-round) RAIN, we further incorporate the idea of the guess-and-determine attack. By guessing the value of the $2^{n/2+1}$ -th power of the input of the middle S-box, we can linearize the S-box and thus the two linear layers of the 3-round RAIN can be combined and regarded as one linear layer. Then using the MITM modeling and polynomial decomposition, we can obtain an equivalent representation of the 3-round RAIN as a univariate polynomial equation with degree at most $2^{2n/3+1}$. Furthermore, we can attack the 3-round RAIN with $2^{160.6}/2^{236.0}/2^{311.1}$ primitive calls for 128/192/256-bit key, respectively.
3. For the full AIM, we observe that all its linear layers can be decomposed using appropriate linearized polynomials and merged into a single linear layer. By using the MITM modeling, we obtain a system of two special forms of bivariate equations. We find that this system has the property of variable isolation mentioned in [40], making it especially suitable for deriving solutions using the resultant-based method. Based on the special parameter settings of AIM, we propose a fast substitution method such that the complexity of the substitution is negligible, and the complexities of the algebraic attacks on the full AIM are primarily determined by computing the resultants and solving univariate polynomial equations. We finally successfully attack the full AIM with $2^{114.0}/2^{163.2}/2^{228.3}$ primitive calls for 128/192/256-bit key, respectively. The results indicate that AIM cannot achieve its security claims.

Organization. In Section 2, we introduce the background knowledge used in this paper, including linearized polynomials and resultants. In Section 3, we describe our algebraic attack on 2-round RAIN based on polynomial decomposition in Section 3.3 and extend the attack to 3-round RAIN by further combining with the guess-and-determine technique in Section 3.4. In Section 4, we discuss how to integrate the MITM modeling and resultant with our approach to attack the full AIM. We end the paper with conclusions in Section 5.

2 Preliminaries

2.1 Notation

Let $q = p^n$ be a prime power and \mathbb{F}_q the finite field with q elements, where p is a prime number and n is a positive integer. We also use n to denote both the security level and the block size, since they are the same both in RAIN and

AIM. Let $\mathbb{F}_q[x_1, x_2, \dots, x_s]$ be the multivariate polynomial ring over \mathbb{F}_q with indeterminates x_1, x_2, \dots, x_s .

Table 1: Time complexities for attacking 2-round, 3-round RAIN, and full AIM, which are given in the number of equivalent calls of the primitives.

Primitives	Techniques	128	192	256

* The attack for 2-round RAIN in [41] additionally considered one linear layer in the last round.

** The so-called polynomial method in [33] is to use the Dinur's methods [16] to solve the low-degree equivalent equations representation of RAIN.

A product of the form $x_1^{k_1} x_2^{k_2} \dots x_s^{k_s}$ is called a term, where all exponents k_1, k_2, \dots, k_s are nonnegative integers. For any $f \in \mathbb{F}_q[x_1, x_2, \dots, x_s]$ with $f \neq 0$, the set of all terms of f is denoted by $T(f)$ and the degree of f , denoted by $\deg(f)$, is defined as the maximum degree among all its terms, i.e.,

$$\deg(f) = \max \left\{ \sum_{j=1}^s k_j \mid x_1^{k_1} x_2^{k_2} \dots x_s^{k_s} \in T(f) \right\}.$$

For $1 \leq i \leq s$, let $\deg_{x_i}(f)$ be the maximum degree of f in variable x_i , that is

$$\deg_{x_i}(f) = \max \left\{ k_i \mid x_1^{k_1} x_2^{k_2} \dots x_s^{k_s} \in T(f) \right\}.$$

2.2 Linearized Polynomial

Definition 1 (Linearized Polynomial and Affine Polynomial). A polynomial of the form $L(x) = \sum_{i=0}^{n-1} \alpha_i x^{p^i}$ with coefficients $\alpha_i \in \mathbb{F}_q$ is called a linearized polynomial over \mathbb{F}_q . A polynomial of the form $A(x) = L(x) + c$ is called an affine polynomial, where $L(x)$ is a linearized polynomial and $c \in \mathbb{F}_q$.

The terminology linearized polynomial stems from the following property:

$$L(a + b) = L(a) + L(b) \text{ for all } a, b \in \mathbb{F}_q,$$

$$c \cdot L(a) = L(c \cdot a) \text{ for all } a \in \mathbb{F}_q \text{ and } c \in \mathbb{F}_p.$$

We can view $x \in \mathbb{F}_q = \mathbb{F}_{p^n}$ as $\hat{x} \in \mathbb{F}_p^n$ when \mathbb{F}_q is regarded as a vector space over \mathbb{F}_p . In this case, a linearized polynomial over \mathbb{F}_q has a one-to-one correspondence with a linear transformation over \mathbb{F}_p , and hence there exists a matrix $M \in \mathbb{F}_p^{n \times n}$ such that $L(x) = M\hat{x}$. Due to the linearity of linearized polynomials, the composition $L_3(x) = L_1(L_2(x))$ of two linearized polynomials $L_1(x)$ and $L_2(x)$ remains a linearized polynomial. For convenience, we sometimes also denote the composition of linearized polynomials as $L_3 = L_1 \circ L_2$.

Our new method, based on polynomial decomposition, requires the target linearized polynomial to be a permutation polynomial (called linearized permutation polynomial). However, not all linearized polynomials satisfy this property. In [31, page 362], it is proved that a linearized polynomial $L(x) = \sum_{i=0}^{n-1} a_i x^{p^i} \in \mathbb{F}_q[x]$ is a permutation polynomial if and only if its Dickson matrix D_L is invertible, where

$$D_L = \begin{pmatrix} a_0 & a_1 & \cdots & a_{n-1} \\ a_{n-1}^2 & a_0^2 & \cdots & a_{n-2}^2 \\ \vdots & \vdots & \vdots & \vdots \\ a_1^{2^{n-1}} & a_2^{2^{n-1}} & \cdots & a_0^{2^{n-1}} \end{pmatrix}.$$

We note that, in [18], the designers impose a critical constraint that all coefficients of the terms of both the linearized polynomials representing the linear layer and its inverse must be non-zero. Furthermore, [18] shows that the inverse of a linearized polynomial $L(x)$ can be explicitly derived through its associated Dickson matrix, that is

$$L^{-1}(x) = \frac{1}{\det(D_L)} \cdot \sum_{i=0}^{n-1} \bar{a}_i x^{2^i},$$

where \bar{a}_i is the $(i, 0)$ -th cofactor of D_L .

2.3 Resultant

The resultant is a powerful tool for solving systems of polynomial equations. In [40], the authors propose a novel algebraic attack method on AO primitives based on the resultant. In this paper, we will also utilize the resultant to eliminate variables.

Definition 2 (Resultant). Let $f(\mathbf{x}, y), g(\mathbf{x}, y) \in \mathbb{F}_q[\mathbf{x}, y]$ with $\mathbf{x} = (x_1, \dots, x_s)$. The resultant of $f(\mathbf{x}, y)$ and $g(\mathbf{x}, y)$ with respect to the indeterminate y , denoted by $R(f, g, y)$, is defined as the determinant of the Sylvester matrix of $f(\mathbf{x}, y)$ and $g(\mathbf{x}, y)$ when considered as polynomials in the single indeterminate y . That is, if $f(\mathbf{x}, y) = \sum_{i=0}^m f_i y^i$ and $g(\mathbf{x}, y) = \sum_{i=0}^n g_i y^i$, where $f_i, g_i \in \mathbb{F}_q[\mathbf{x}]$, then

3 Improved Algebraic Attacks on RAIN

In this section, we present improved algebraic attacks on 2-round and 3-round RAIN. The MPC-friendly cipher RAIN[18] was first proposed at CCS 2022 and designed as the one-way function for the post-quantum signature scheme Rainier. We start with a brief introduction to RAIN.

3.1 Description of RAIN

The schematic of the r -round RAIN is depicted in Fig. 1, where the plaintext p and ciphertext c are public, while the key k is kept secret. The security of RAIN relies on the difficulty of solving the key from a single pair of plaintext and ciphertext. Let R_i denote the permutation in the i -th round, defined as

$$R_i = M_i(S(x + k + c_i)), 1 \leq i \leq r - 1,$$

where $c_i \in \mathbb{F}_{2^n}$ is the round constant and $M_i \in \mathbb{F}_2^{n \times n}$ is the linear-layer matrix used in the i -th round. Note that the “+” operation denotes the “ \oplus ” operation as done in the original paper. The permutation in the final round is given by

$$R_r = S(x + k + c_r) + k.$$

Each $M_i(1 \leq i \leq r - 1)$ is constructed from a linearized polynomial over \mathbb{F}_{2^n} , expressed as

$$L_i(x) = \sum_{j=0}^{n-1} d_{i,j} x^{2^j}.$$

All the coefficients in both $L_i(x)$ and its inverse $L_i^{-1}(x)$ are non-zero, which means that $\deg(L_i(x)) = \deg(L_i^{-1}(x)) = 2^{n-1}$. The S-box $S : \mathbb{F}_{2^n} \rightarrow \mathbb{F}_{2^n}$ is defined by

$$S(x) = x^{2^n-2} = \begin{cases} x^{-1}, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0. \end{cases}$$

For simplicity, we define $0^{-1} = 0$. Furthermore, **we simply use x^{-1} to represent the S-box throughout the rest of paper**, when there is no ambiguity.

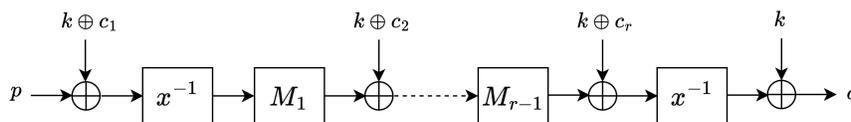

Fig. 1: The r -round RAIN

Concrete Instances. The designers instantiate three variants of RAIN targeted for 128, 192, and 256 bits of security, respectively. Two security levels for each variants are recommended with the round number as 3 or 4. The parameters and irreducible polynomials for constructing the corresponding finite fields are shown in Table 2.

Table 2: Three instantiations of RAIN

scheme	security level (block size)	round	finite field polynomial over \mathbb{F}_2
RAIN-128	128	{3, 4}	$\mathbb{F}_{2^{128}} : X^{128} + X^7 + X^2 + X + 1$
RAIN-192	192	{3, 4}	$\mathbb{F}_{2^{192}} : X^{192} + X^7 + X^2 + X + 1$
RAIN-256	256	{3, 4}	$\mathbb{F}_{2^{256}} : X^{256} + X^{10} + X^5 + X^2 + 1$

3.2 Existing Cryptanalysis of RAIN

In this subsection, we mainly review the cryptanalysis results of the 2-round and 3-round RAIN. We note that the main idea of existing attacks on RAIN is converting the problem into solving systems of linear or quadratic equations over \mathbb{F}_2 . In Asiacrypt 2023 [41], Zhang et al. proposed that the multiplicative inverse function x^{-1} can be linearized by guessing the value of its input to a specific power x^d . For 2-round RAIN, the authors selected a suitable value of d that divides $2^n - 1$, then constructed an overdefined system of equations and solved the system using linearization techniques. In FSE 2024 [33], Liu et al. pointed out that it is feasible to construct a low-degree equation system to describe 2-round RAIN, then employed the Dinur’s method [16] or the crossbred method [27] to solve the well-determined or over-determined system, respectively.

For 3-round RAIN, the designers of AIM proposed using Gröbner basis attacks and XL attacks to analyze its security in [30]. Liu et al. in Asiacrypt 2024 [32] improved the modeling approach in [30] to derive more equations for constructing an over-determined system and thus reducing the complexity of Gröbner basis attacks.

The main barrier of the previous work over \mathbb{F}_2 lies in the number of S-boxes: typically, a larger number of S-boxes indicates a higher attacking complexity. As a comparison, we model RAIN over \mathbb{F}_{2^n} and the influence of the number of S-boxes is much smaller, instead, we need to carefully deal with the linear layers. Specifically, we decompose the linearized polynomial of the linear layer into composition of low-degree polynomials and obtain equations with much lower degrees. For 2-round RAIN, we can construct an equivalent univariate polynomial equation with a degree no more than $2^{n/2+2}$. By further combining the method of polynomial decomposition with guess-and-determine techniques, we can extend our attack to 3-round RAIN. As the complexities of our attacks mainly lie in finding the roots of univariate polynomials and computing resultants, the evaluations of complexities are accurate.

3.3 Improved Algebraic Attack on 2-round RAIN

In this subsection, we present improved algebraic attacks on 2-round RAIN using decomposition of linearized polynomials.

Inspiration of Decomposition of Linearized Polynomials. Our idea for decomposition of the linearized polynomials is inspired by the design of Jarvis [7]. The round function of Jarvis is shown in Fig. 2, in which the linear layer is constructed from the composition of two quartic affine polynomials $B(x)$ and $C(x)$, i.e., $A = C \circ B^{-1}$, where

$$\begin{aligned} B(x) &= x^4 + b_2x^2 + b_1x + b_0, \\ C(x) &= x^4 + c_2x^2 + c_1x + c_0, \end{aligned}$$

with $b_2, b_1, b_0, c_2, c_1, c_0 \in \mathbb{F}_{2^n}$.

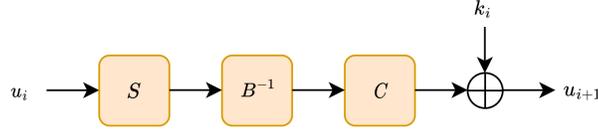

Fig. 2: The i -th round of the Jarvis block cipher.

In Asiacrypt 2019 [2], low-degree representation for Jarvis was proposed and used to break its security claims. In Asiacrypt 2024 [40], Yang et al. further proposed to use the resultant to solve the equations of the low-degree representation of Jarvis. Motivated by these work, we wonder if the high-degree linear layers of RAIN could be represented as compositions of low-degree linearized polynomials, such that we can employ the tools such as the resultant to solve the derived system. Below we show how we achieve it for RAIN.

Meet-in-the-Middle (MITM) Modeling for 2-round RAIN. The meet-in-the-middle modeling for 2-round RAIN is illustrated in Fig. 3, where M_1 is the original linear-layer matrix while M_a is another nonsingular matrix of a low degree that we introduced. We append M_a^{-1} , the inverse of M_a , immediately after M_a to cancel out the influence of the introduction of M_a . Let $L_1(x)$ and $L_a(x)$ denote the linearized polynomials corresponding to M_1 and M_a , respectively. Denote $L_\alpha(x) = L_a(L_1(x))$ and the goal is to find a low-degree L_a such that L_α also has a low degree. It is worth noting that we do not directly construct the matrix M_a , instead, we find linearized polynomials by solving a system of linear equations in the coefficients of the polynomials. We will elaborate the process later on.

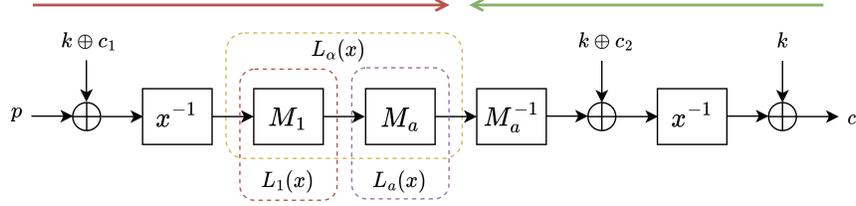

Fig. 3: MITM modeling for 2-round RAIN

After we have found an appropriate L_a , we employ the MITM modeling to construct equations for k . Specifically, we regard p, c as knowns and run the cipher forward and backward, respectively, and then meet in the middle at where the value should be identical. Then we can derive the equation below

$$L_\alpha\left(\frac{1}{p+k+c_1}\right) = L_a\left(\frac{1}{c+k} + k + c_2\right). \quad (1)$$

Construct Low-degree Decomposition of Linearized Polynomials. We now show how we decompose a linearized polynomial into the composition of two low-degree polynomials, i.e., how we find low-degree $L_a(x)$ and L_α in Fig. 3. The degree of Equation (1) relies on the degrees of L_a and L_α . Let

$$L_a(x) = \sum_{i=0}^{n-1} a_i x^{2^i}, \quad L_1(x) = \sum_{j=0}^{n-1} d_{1,j} x^{2^j},$$

where $d_{1,j}$'s are known while a_i 's are the unknowns to be solved. It is clear that

$$\begin{aligned} L_\alpha(x) &= L_a(L_1(x)) = \sum_{i=0}^{n-1} a_i \left(\sum_{j=0}^{n-1} d_{1,j} x^{2^j}\right)^{2^i} \\ &= \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} a_i d_{1,j}^{2^i} x^{2^{(i+j) \bmod n}}. \end{aligned}$$

If we expect that $\deg(L_a(x)) \leq 2^l$ and $\deg(L_\alpha(x)) \leq 2^\gamma$ for some integers $0 \leq l, \gamma \leq n-1$, then we can obtain the following system of linear equations

$$\begin{cases} a_i = 0 & \text{for } l+1 \leq i \leq n-1, \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t \pmod n}} a_i d_{1,j}^{2^i} = 0 & \text{for } \gamma+1 \leq t \leq n-1. \end{cases} \quad (2)$$

After removing the a_i 's that are zero, Equation (2) can be simplified to a system of $n-\gamma-1$ linear equations with $l+1$ unknowns, i.e., a_0, a_1, \dots, a_l . To guarantee

a non-zero solution, l and γ should satisfy that $l + 1 > n - \gamma - 1$, or equivalently, $l + \gamma > n - 2$. Furthermore, to minimize the degree of Equation (1), we prefer γ and l to be as close as possible. In our experiments, we start to select $l = n/2 - 1$ and $\gamma = n/2$. Once the values of γ and l are determined, we can solve the system of linear equations. When we have derived a solution vector $\mathbf{a} = (a_0, a_1, \dots, a_l)$, we check if the Dickson matrix mentioned in Section 2.2 is invertible. If not, we try a different solution or increase the null space by increasing the values of l and γ until we find one satisfying the requirements, which indicates that we get a pair of $L_a(x)$ and $L_\alpha(x)$ with degrees below the thresholds we have set. According to the experiments performed for the linearized polynomials chosen for RAIN, we observed that l will not exceed $n/2$ and γ will not exceed $n/2 + 1$.

Key Recovery. After we have found L_a and L_α , we can solve the univariate polynomial equation in Equation (1) using the method described in Section 2.4 and recover the secret key k .

Complexity Analysis. The complexity of finding one solution of Equation (2) does not exceed $\mathcal{O}(n^\omega)$ and can be neglected. Therefore, we below mainly focus on the complexity of solving Equation (1).

Let L_a^* and L_α^* be the reciprocal polynomials of L_a and L_α , which are defined by

$$L_a^*(x) = x^{\deg(L_a)} L_a\left(\frac{1}{x}\right),$$

$$L_\alpha^*(x) = x^{\deg(L_\alpha)} L_\alpha\left(\frac{1}{x}\right),$$

respectively. Using the linearity of linearized polynomials, Equation (1) can be rewritten as below

$$L_\alpha\left(\frac{1}{p+k+c_1}\right) = L_a\left(\frac{1}{c+k}\right) + L_a(k+c_2),$$

or equivalently,

$$L_\alpha\left(\frac{1}{p+k+c_1}\right) + L_a\left(\frac{1}{c+k}\right) + L_a(k+c_2) = 0.$$

Multiplying both sides of the equation by $(p+k+c_1)^{2^\gamma} (c+k)^{2^l}$ to eliminate the denominators, we have

$$(p+k+c_1)^{2^\gamma} \cdot (c+k)^{2^l} \cdot \left(L_\alpha\left(\frac{1}{p+k+c_1}\right) + L_a\left(\frac{1}{c+k}\right) + L_a(k+c_2) \right) = 0,$$

or equivalently,

$$G(k) := (p+k+c_1)^{2^\gamma} \cdot L_a^*(c+k) + (c+k)^{2^l} \cdot L_\alpha^*(p+k+c_1) \\ + (p+k+c_1)^{2^\gamma} \cdot (c+k)^{2^l} \cdot L_a(k+c_2) = 0.$$

Since $\deg(L_a^*) < 2^l$ and $\deg(L_\alpha^*) < 2^\gamma$, it follows that

$$\deg(G(k)) \leq 2^\gamma + 2^l + 2^l = 2^\gamma + 2^{l+1}.$$

In our experiments, we observe that l and γ will not exceed $n/2$ and $n/2 + 1$, respectively, so that $\deg(G(k))$ will not exceed $2^{n/2+2}$. According to Section 2.4, the complexity of solving $G(k)$ will not exceed

$$\mathcal{O}\left(2^{n/2+2}(n/2 + 2)(n/2 + 2 + \log q \log(n/2 + 2))\right). \quad (3)$$

The complexity above is expressed in terms of the number of field operations denoted as T . For fair comparison with [33,41], we also convert all complexity estimates into bit operations T_{bit} and number of encryptions T_{enc} . Specifically:

- A field multiplication over \mathbb{F}_{2^n} is equivalent to n^2 bit operations,
- A field addition over \mathbb{F}_{2^n} is equivalent to n bitwise XOR operations,
- One call of primitives over \mathbb{F}_{2^n} is equivalent to n^3 bit operations [41, Page 14].

For simplicity, we uniformly equate one field operation to n^2 bit operations. Therefore, we have $T_{bit} = n^2 \cdot T$ and $T_{enc} = T/n$.

Experimental Verification We generated the linearized polynomial L_1 using the `rain_instance_gen.sage` program provided in [18] for 2-round RAIN. We started with $l = n/2 - 1$, $\gamma = n/2$ and got the concrete linearized permutation polynomials L_a and L_α that satisfy $L_1 = L_\alpha \circ L_a^{-1}$. The degrees of L_a and L_α are $2^{63}/2^{95}/2^{127}$ and $2^{64}/2^{97}/2^{128}$, respectively, for RAIN-128/192/256. Based on the experimental results, the degrees of the linearized polynomials derived through polynomial decomposition and the time complexities are shown in Table 3.

We also verified the correctness of our novel attack on all variants of 2-round RAIN over small finite fields (e.g., $\mathbb{F}_{2^{30}}$). In our experiments, we observed the existence of pseudo-keys, meaning that a single pair of plaintext and ciphertext might yield more than two keys. That is, a pseudo-key can also encrypt the same plaintext to the same ciphertext as the actual key. However, the number of pseudo-keys is very limited.

Table 3: Time complexities of our attacks on 2-round RAIN

Scheme	n	l	γ	T	T_{bit}	T_{enc}
RAIN-128	128	2^{63}	2^{64}	$2^{80.7}$	$2^{94.7}$	$2^{73.7}$
RAIN-192	192	2^{95}	2^{97}	$2^{114.6}$	$2^{129.8}$	$2^{107.0}$
RAIN-256	256	2^{127}	2^{128}	$2^{146.9}$	$2^{162.9}$	$2^{138.9}$

3.4 Attacks on 3-round RAIN Combined with the Guess-and-determine Attack

It is natural to consider how to extend our attack to 3-round RAIN. However, due to the presence of two linear-layer matrices that are separated by one S-box in 3-round RAIN, it is hard to trivially connect them together and directly apply our method. To address this issue, we employ the linearization technique for x^{-1} proposed by Zhang et al in [41].

Linearization Technique for x^{-1} . For even n , the multiplicative inverse function x^{-1} can be linearized by guessing $2^{n/2} - 1$ possible values for x^d , where $d = 2^{n/2} + 1$. More specifically, the x^{-1} over \mathbb{F}_{2^n} can be represented as

$$x^{2^n-2} = (x^{2^{n/2}+1})^{2^{n/2}-2} \cdot x^{2^{n/2}}.$$

Once the value of $(x^{2^{n/2}+1})^{2^{n/2}-2}$ is guessed, x^{2^n-2} becomes a linearized polynomial.

MITM Modeling for 3-round RAIN. Fig. 4 illustrates the MITM modeling for 3-round RAIN, where M_1 and M_2 are the original linear-layer matrices while M_a and M_b are two nonsingular matrices we introduced. Similarly, to cancel out the influence of M_a and M_b , we add their inverses right before or after them, respectively. Let $L_1(x), L_2^{-1}(x), L_a(x)$, and $L_b(x)$ denote the linearized polynomials corresponding to M_1, M_2^{-1}, M_a , and M_b , respectively. Denote $L_\alpha(x) = L_a(L_1(x))$, $L_\beta(x) = L_b(L_2^{-1}(x))$, and the input of the second S-box as variable v . We apply meet-in-the-middle modeling between the red and first green arrows, as well as between the yellow and the second green arrows, respectively. Hence, we derive a system of bivariate equations as below

$$\begin{cases} L_\alpha\left(\frac{1}{p+k+c_1}\right) = L_a(k + c_2 + v) \\ L_\beta\left(\frac{1}{c+k} + k + c_3\right) = L_b\left(\frac{1}{v}\right) \end{cases}. \quad (4)$$

Extracting a Univariate Equation from Equation (4). To eliminate the variable v , we rewrite Equation (4) as below

$$\begin{cases} L_\alpha\left(\frac{1}{p+k+c_1}\right) + L_a(k + c_2) = L_a(v) \\ L_\beta\left(\frac{1}{c+k} + k + c_3\right) = L_b\left(\frac{1}{v}\right) \end{cases}. \quad (5)$$

We can linearize the second S-box by guessing the value of $v^{2^{n/2}+1}$. More precisely, suppose that $v^{2^{n/2}+1} = \eta$, let $\theta = \eta^{2^{n/2}-2}$, then it is clear that $\eta, \theta \in \mathbb{F}_{2^{n/2}}^*$, and

$$L_b\left(\frac{1}{v}\right) = L_b(v^{2^n-2}) = L_b(\eta^{2^{n/2}-2}v^{2^{n/2}}) = L_b(\theta v^{2^{n/2}}).$$

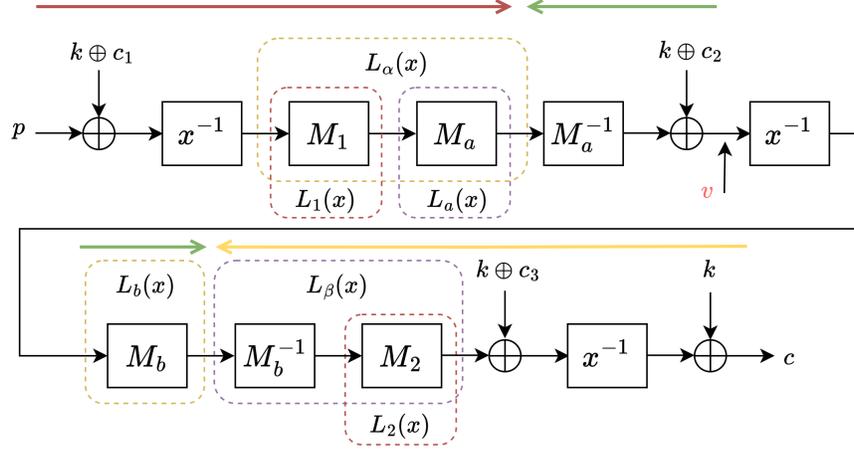

Fig. 4: MITM modeling for 3-round RAIN

We can rewrite Equation (5) as:

$$\begin{cases} L_\alpha\left(\frac{1}{p+k+c_1}\right) + L_a(k+c_2) = L_a(v) \\ L_\beta\left(\frac{1}{c+k}\right) + L_\beta(k+c_3) = L_b(\theta v^{2^{n/2}}) \end{cases} \quad (6)$$

By guessing the value of θ , we can transform $L_b(\theta v^{2^{n/2}})$ into a linearized polynomial, the next step is to solve the coefficients of L_a and L_b to make $L_a(v) = L_b(\theta v^{2^{n/2}})$. Let

$$\begin{aligned} L_\alpha(x) &= \sum_{i=0}^{n-1} a_i x^{2^i}, \quad L_b(x) = \sum_{i=0}^{n-1} b_i x^{2^i}, \\ L_1(x) &= \sum_{j=0}^{n-1} d_{1,j} x^{2^j}, \quad L_2^{-1}(x) = \sum_{j=0}^{n-1} d'_{2,j} x^{2^j}, \end{aligned}$$

then we have

$$\begin{aligned} L_\alpha(x) &= L_a(L_1(x)) = \sum_{i=0}^{n-1} a_i \left(\sum_{j=0}^{n-1} d_{1,j} x^{2^j} \right)^{2^i} = \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} a_i d_{1,j}^{2^i} x^{2^{(i+j) \bmod n}}, \\ L_\beta(x) &= L_b(L_2^{-1}(x)) = \sum_{i=0}^{n-1} b_i \left(\sum_{j=0}^{n-1} d'_{2,j} x^{2^j} \right)^{2^i} = \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} b_i d'_{2,j}^{2^i} x^{2^{(i+j) \bmod n}}, \end{aligned}$$

where $d_{1,j}$'s, $d'_{2,j}$'s are known, while a_i 's, b_i 's are unknowns to be solved. To eliminate v , we need $L_a(v) = L_b(\theta v^{2^{n/2}})$, which yields

$$a_{(i+n/2) \bmod n} = b_i \theta^{2^i} \quad \text{for } 0 \leq i \leq n-1. \quad (7)$$

In other words, if the equations in Equation (7) have solutions, we can eliminate the variable v . After v is eliminated, we add the two equations in Equation (6) and derive the equation below

$$L_\alpha\left(\frac{1}{p+k+c_1}\right) + L_a(k+c_2) + L_\beta\left(\frac{1}{c+k}\right) + L_\beta(k+c_3) = 0. \quad (8)$$

Construct Low-degree Decomposition of Linearized Polynomials. Suppose we expect that $\deg(L_a(x)) \leq 2^l$, $\deg(L_\alpha(x)) \leq 2^\gamma$, and $\deg(L_\beta(x)) \leq 2^\lambda$ for some integers $0 \leq l, \lambda, \gamma \leq n-1$, then we can obtain the following system of linear equations

$$\begin{cases} a_i = 0 & \text{for } l+1 \leq i \leq n-1 \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t_1 \pmod n}} a_i d_{1,j}^{2^i} = 0 & \text{for } \gamma+1 \leq t_1 \leq n-1 \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t_2 \pmod n}} b_i d'_{2,j} 2^{2^i} = 0 & \text{for } \lambda+1 \leq t_2 \leq n-1 \end{cases}. \quad (9)$$

There are a total of $2n$ variables $\mathbf{u} = (a_0, a_1, \dots, a_{n-1}, b_0, b_1, \dots, b_{n-1})$ and $4n - \gamma - \lambda - l - 3$ equations in Equations (7) and (9). To ensure that the system of equations has a non-zero solution, the number of variables should be larger than the number of equations, i.e., $\lambda + \gamma + l + 3 > 2n$. To minimize the degree of the targeted equation in Equation (8), we aim to make γ , λ , and l as close as possible. In practice, we start by choosing $l = \lceil 2n/3 - 1 \rceil$, $\gamma = \lceil 2n/3 - 1 \rceil$, and $\lambda = \lceil 2n/3 \rceil$.

The Steps and Complexities of Our Attacks. Our attacks and complexities on 3-round RAIN can be outlined as follows.

1. **Eliminating the intermediate variable v through enumerating θ .** Let g be a generator of $\mathbb{F}_{2^n}^*$. Then any element in $\mathbb{F}_{2^n}^*$ can be represented as g^i , $0 \leq i \leq 2^n - 2$. The values of $\theta \in \mathbb{F}_{2^{n/2}}^* = \left\{ g^{i \cdot (2^{n/2} + 1)} : i = 0, \dots, 2^{n/2} - 2 \right\}$. Therefore, we directly assign θ the value of $g^{i \cdot (2^{n/2} + 1)}$.
2. **Solving L_a and L_b .** This step involves solving a linear system derived from Equations (7) and (9). For each solution derived, we check if the Dickson polynomials of L_a and L_b are invertible. Therefore, the complexity of this step can be estimated as $\delta \cdot \mathcal{O}((2n)^\omega)$, where δ denotes the number that one repeats the solving and checking process. In experiments, δ is small, indicating that we only need to try few times. Therefore, the time complexity of this step is negligible compared to the complexity of solving the univariate polynomial below.
3. **Solving Equation (8).** Similar to Equation (1), by eliminating the denominators, we can obtain a univariate equation in terms of the key k for 3-round

RAIN as

$$G(k) := (c+k)^{2^\lambda} \cdot L_\alpha^*(p+k+c_1) + (p+k+c_1)^{2^\gamma} \cdot L_\beta^*(c+k) \\ + (c+k)^{2^\lambda} \cdot (p+k+c_1)^{2^\gamma} \cdot (L_a(k+c_2) + L_\beta(k+c_3)) = 0,$$

where L_α^* and L_β^* are the reciprocal polynomials of L_α and L_β , respectively. In our experiments, we have $l, \gamma, \lambda \leq \lceil \frac{2}{3}n \rceil$. The degree of $G(k)$ satisfies that $\deg(G(k)) \leq \max(2^l + 2^\lambda + 2^\gamma, 2^{\lambda+1} + 2^\gamma) \leq 2^{\lceil \frac{2}{3}n \rceil + 2}$.

Therefore, the time complexity of our attack can be evaluated as

$$\mathcal{O}\left((2^{n/2} - 1) \cdot (d \log d (\log d + \log q \log \log d))\right), \quad (10)$$

where $d = 2^{\lceil \frac{2}{3}n \rceil + 2}$.

Experimental Verification. For 3-round RAIN, we generated the linearized polynomials L_1 and L_2 using the `rain_instance_gen.sage` program provided in [18]. Due to the large size of the finite field, we cannot traverse all possibilities of θ . However, through experiments on small finite fields and verifications under some guessed values of θ on RAIN-128/192/256, we found that when $l, \gamma, \lambda \leq \lceil \frac{2}{3}n \rceil$, there always exist linearized permutation polynomials L_a, L_α, L_b , and L_β such that $L_1 = L_\alpha \circ L_a^{-1}$ and $L_2 = L_\beta \circ L_b^{-1}$. Therefore, it is appropriate to use $2^{\lceil \frac{2}{3}n \rceil + 2}$ to estimate the degree of $G(k)$ after each guess. Based on the experimental results, we set $l = \gamma = \lambda = \lceil \frac{2}{3}n \rceil$ and the time complexities for attacking different variants of 3-round RAIN are shown in Table 4. Furthermore, we also verified the correctness of our novel attack on all variants of 3-round RAIN over small finite fields (e.g., $\mathbb{F}_{2^{18}}$).

Table 4: Time complexities of attacking 3-round RAIN

Scheme	n	l	γ	λ	T	T_{bit}	T_{enc}
RAIN-128	128	2^{86}	2^{86}	2^{86}	$2^{167.6}$	$2^{181.6}$	$2^{160.6}$
RAIN-192	192	2^{128}	2^{128}	2^{128}	$2^{243.6}$	$2^{258.7}$	$2^{236.0}$

4 Attacks on Full AIM Combined with the Resultant and Substitution Theory

We observed that AIM [30] has a similar linear layer to RAIN and thus we can extend the idea of polynomial decomposition to AIM. However, the S-boxes $x^{2^{e_i}-1}$ in AIM are quite different to those in RAIN. Specifically, the inverses of the S-boxes in AIM have high degrees, and correspondingly, the constructed

equations in the backward direction would have high degrees when using the MITM modeling. Therefore, we adopt the substitution theory and resultant in [40] to reduce the degrees of equations and derive a univariate polynomial for AIM.

4.1 Description of AIM

The general construction of AIM is illustrated in Fig. 5. It takes a secret k as the input of several (say $m - 1$) parallel branches each consisting of an S-box and a linear layer, and uses all the outputs to produce a public output y through an additional S-box. The S-boxes have the form of $x^{2^{e_i}-1}$ ($i = 1, 2, \dots, m$) where e_i 's are distinct prime numbers for which $2^{e_i} - 1$ are Mersenne primes. The linear layer $B_i(x)$ can be expressed as $B_i(x) = L_i(x) + c_i$, with $L_i(x)$ being a linearized polynomial over \mathbb{F}_q and $c_i \in \mathbb{F}_q$. Denote

$$z_i = k^{2^{e_i}-1} \text{ for } i = 1, 2, \dots, m - 1,$$

then the output y can be represented as:

$$y = \left(\sum_{i=1}^{m-1} B_i(z_i) \right)^{2^{e_m}-1} + k.$$

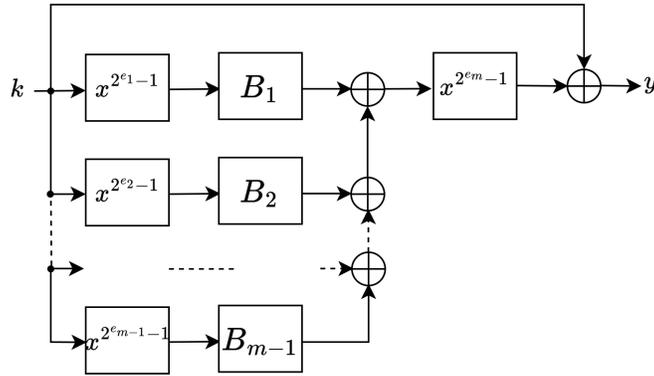

Fig. 5: The general construction of AIM

Parameter Sets. The extension fields $\mathbb{F}_{2^{128}}$, $\mathbb{F}_{2^{192}}$, and $\mathbb{F}_{2^{256}}$ are constructed using the same irreducible polynomials over \mathbb{F}_2 as those specified in RAIN (see Subsection 3.1). Other parameters are presented in Table 5.

Table 5: Parameters sets of AIM

Scheme	n	m	e_1	e_2	e_3	e_4
AIM-I	128	3	3	27	5	-
AIM-III	192	3	5	29	7	-
AIM-V	256	4	3	53	7	5

4.2 Algebraic Attacks on AIM-I/III

Our improved algebraic attack applies to all variants of AIM. In this section, we first focus on AIM-I/III (with $m = 3$) to illustrate our attack.

MITM Modeling for AIM-I/III. Fig. 6 presents the MITM modeling of AIM-I/III. As defined, $B_i(x) = L_i(x) + c_i$, where $L_i(x)$ is a linearized polynomial for $i = 1, 2$. We introduce a linearized polynomial denoted as $L_a(x)$ aiming to get two low-degree linearized polynomials $L_{\alpha_1}(x)$ and $L_{\alpha_2}(x)$ as below

$$L_{\alpha_1}(x) = L_a(L_1(x)), L_{\alpha_2}(x) = L_a(L_2(x)).$$

Note that we introduce the same linearized polynomial $L_a(x)$ for both $L_1(x)$ and $L_2(x)$ to reduce the number of variables. Similarly, we additionally introduce $L_a^{-1}(x)$ right after $L_a(x)$ to cancel out the influence of $L_a(x)$. We also introduce two variables v_1 and v_2 after the linear layers as shown in Fig. 6.

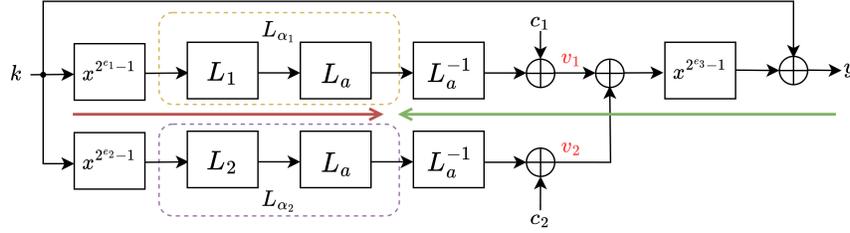

Fig. 6: MITM modeling for AIM-I/III

As shown in Fig. 6, we construct equations at the intersection of the red and green arrows as well as at the last S-box as below

$$\begin{cases} L_{\alpha_1}(k^{2^{e_1}-1}) = L_a(v_1 + c_1) \\ L_{\alpha_2}(k^{2^{e_2}-1}) = L_a(v_2 + c_2) \\ (v_1 + v_2)^{2^{e_3}-1} = y + k \end{cases} . \quad (11)$$

Let $v = v_1 + v_2, c = c_1 + c_2$, then Equation (11) can be transformed into the following form by adding the first two equations

$$\begin{cases} L_{\alpha_1}(k^{2^{e_1}-1}) + L_{\alpha_2}(k^{2^{e_2}-1}) + L_a(c) = L_a(v) \\ v^{2^{e_3}-1} = y + k \end{cases} \quad (12)$$

Constructing Low-degree Equations. We now proceed to get low-degree representation for Equation (12). Precisely, let

$$L_a(x) = \sum_{i=0}^{n-1} a_i x^{2^i}, \quad L_1(x) = \sum_{j=0}^{n-1} d_{1,j} x^{2^j}, \quad L_2(x) = \sum_{j=0}^{n-1} d_{2,j} x^{2^j},$$

where $d_{1,j}$'s, $d_{2,j}$'s $\in \mathbb{F}_q$ are known coefficients, while a_i 's $\in \mathbb{F}_q$ are the unknowns to be determined. Then $L_{\alpha_1}(x)$ and $L_{\alpha_2}(x)$ can be represented as:

$$\begin{cases} L_{\alpha_1}(x) = L_a(L_1(x)) = \sum_{i=0}^{n-1} a_i (\sum_{j=0}^{n-1} d_{1,j} x^{2^j})^{2^i} \\ L_{\alpha_2}(x) = L_a(L_2(x)) = \sum_{i=0}^{n-1} a_i (\sum_{j=0}^{n-1} d_{2,j} x^{2^j})^{2^i} \end{cases} \quad .$$

If we expect that

$$\deg(L_a(x)) \leq 2^l, \deg(L_{\alpha_1}(x)) \leq 2^\gamma, \deg(L_{\alpha_2}(x)) \leq 2^\lambda$$

for some integers $0 \leq l, \gamma, \lambda \leq n-1$, then we can obtain the following system of linear equations:

$$\begin{cases} a_i = 0 \quad \text{for } l+1 \leq i \leq n-1 \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t_1 \pmod n}} a_i d_{1,j}^{2^i} = 0 \quad \text{for } \gamma+1 \leq t_1 \leq n-1 \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t_2 \pmod n}} a_i d_{2,j}^{2^i} = 0 \quad \text{for } \lambda+1 \leq t_2 \leq n-1 \end{cases} \quad (13)$$

After removing the a_i variables that are zero, Equation (13) can be simplified to a system of $2n - \gamma - \lambda - 2$ linear equations with $l+1$ unknowns. To guarantee a non-zero solution, the number of variables should be larger than that of equations, i.e., $l + \gamma + \lambda + 3 > 2n$.

Extracting a Univariate Equation. Next, we eliminate the variable v in Equation (12) to obtain a univariate polynomial with respect to k . Equation (12) has the property of variable isolation mentioned in [40], meaning that there are no cross terms between variables v and k and the powers of v can be substituted by an expression of k . Therefore, the resultant and substitution theory can be well applied to achieve the goal. However, directly applying the resultant to eliminate v would lead to high computational complexity, as the resulting linearized polynomial would have an excessively large degree. To mitigate this, we first employ the substitution theory to reduce the degree of v below $2^{e_3} - 1$. Specifically,

we substitute $v^{2^{e_3}-1} = y + k$ into the linearized polynomial $L_a(v) = \sum_{i=0}^l a_i v^{2^i}$. For each $e_3 \leq i \leq l$, the term v^{2^i} can be rewritten as

$$v^{2^i} = (v^{2^{e_3}-1})^{s_i} v^{r_i} = (y + k)^{s_i} v^{r_i},$$

where $r_i < 2^{e_3} - 1$, $s_i < 2^{i-e_3+1}$, and $(2^{e_3} - 1)s_i + r_i = 2^i$. In practice, we use the substitution $v^{2^{e_3}} = v \cdot (y + k)$ rather than $v^{2^{e_3}-1} = y + k$ to improve the computational efficiency. To illustrate this, consider the substitution for v^{2^l} , which yields:

$$\begin{aligned} v^{2^l} &= (v^{2^{e_3}})^{2^{l-e_3}} \\ &= v^{2^{l-e_3}} \cdot (y + k)^{2^{l-e_3}} \\ &= v^{2^{l-2e_3}} \cdot (y + k)^{2^{l-e_3} + 2^{l-2e_3}} \\ &= \dots \\ &= v^{2^{l-s \cdot e_3}} \cdot (y + k)^{2^{l-e_3} + 2^{l-2e_3} + \dots + 2^{l-s \cdot e_3}} \\ &= v^{2^r} \cdot (y + k)^{2^{l-e_3} + 2^{l-2e_3} + \dots + 2^{l-s \cdot e_3}} \\ &= v^{2^r} \cdot \prod_{j=1}^s (y^{2^{l-j \cdot e_3}} + k^{2^{l-j \cdot e_3}}), \end{aligned} \tag{14}$$

where s and r are the unique integers such that $l = s \cdot e_3 + r$ with $0 \leq r < e_3$.

Denote the expression of $L_a(v)$ after substitution as $h(v, k)$, we have $\deg_k(h) < 2^{l-e_3+1}$ and $\deg_v(h) < 2^{e_3} - 1$. Let

$$\begin{cases} f(k, v) := L_{\alpha_1}(k^{2^{e_1}-1}) + L_{\alpha_2}(k^{2^{e_2}-1}) + L_a(c) + h(v, k) = 0 \\ g(k, v) := v^{2^{e_3}-1} + y + k = 0 \end{cases}, \tag{15}$$

where $\deg_k(f)$ is bounded by

$$D := \deg_k(f) \leq \max((2^{e_1} - 1)2^\gamma, (2^{e_2} - 1)2^\lambda, 2^{l-e_3+1}). \tag{16}$$

The next step is to compute $G(k) = R(f, g, v)$. According to Definition 2, the size of the Sylvester determinant corresponding to $R(f, g, v)$ is at most $(2^{e_3+1} - 3) \times (2^{e_3+1} - 3)$. In this determinant, each entry in the first $2^{e_3} - 2$ rows contains the variable k with degree D , while each entry in the remaining $2^{e_3} - 1$ rows contains k with degree 1. Consequently, the degree of $G(k)$ is bounded by

$$\deg(G(k)) \leq D(2^{e_3} - 2) + 2^{e_3} - 1.$$

The complexities of resultant computation and root-finding for $G(k)$ are both highly dependent on D . As shown later, these two steps dominate the computational cost, far exceeding that of the substitution step. Thus, our objective reduces to selecting optimal values for γ , λ , and l to minimize D . From (16), this requires balancing $(2^{e_1} - 1)2^\gamma$, $(2^{e_2} - 1)2^\lambda$, and 2^{l-e_3+1} as close as possible under the condition $l + \gamma + \lambda + 3 > 2n$. Neglecting lower-order terms, we aim for

By performing Gaussian elimination on the first $2^{e_3} - 2$ rows using the pivot elements 1 in the last $2^{e_3} - 1$ rows, we simplify the resultant to

$$R(f, g, v) = \begin{vmatrix} f_0 & f_{2^{e_3}-2}g_0 & \cdots & f_2g_0 & f_1g_0 \\ f_1 & f_0 & \cdots & f_3g_0 & f_2g_0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ f_{2^{e_3}-3} & f_{2^{e_3}-4} & \cdots & f_0 & f_{2^{e_3}-2}g_0 \\ f_{2^{e_3}-2} & f_{2^{e_3}-3} & \cdots & f_1 & f_0 \end{vmatrix}, \quad (18)$$

where each entry of (18) has degree at most $D + 1$. Thus, the complexity of this step can be estimated as

$$\mathcal{O}\left((D+1)(\log(D+1))^2(2^{e_3}-1)^\omega\right).$$

4. **Solving $G(k)$.** Let $\deg(G(k)) = d$, then we have

$$\deg(d) \leq D(2^{e_3} - 2) + 2^{e_3} - 1 \leq 2^{\lceil(2n-2+e_1+e_2-e_3)/3\rceil} \cdot (2^{e_3} - 2) + 2^{e_3} - 1.$$

The overall time complexity of our attack on AIM-I/III can be estimated as

$$\mathcal{O}\left((D+1)(\log(D+1))^2(2^{e_3}-1)^\omega + d \log d(\log d + \log q \log \log d)\right).$$

4.3 Algebraic Attack on AIM-V

The attack for AIM-I/III can be naturally extended to AIM-V (with $m = 4$). Below, we provide a brief introduction to the algebraic attack on AIM-V and Fig. 7 presents the MITM modeling. Using the notations introduced earlier, we define L_{α_1} , L_{α_2} , and L_{α_3} as follows:

$$L_{\alpha_1} = L_a \circ L_1, L_{\alpha_2} = L_a \circ L_2, L_{\alpha_3} = L_a \circ L_3.$$

We further introduce intermediate variables v_1 , v_2 , and v_3 after the linear layer in each branch as shown in Fig. 7.

Then we can construct equations for each branch and the output as below

$$\begin{cases} L_{\alpha_1}(k^{2^{e_1}-1}) = L_a(v_1 + c_1) \\ L_{\alpha_2}(k^{2^{e_2}-1}) = L_a(v_2 + c_2) \\ L_{\alpha_3}(k^{2^{e_3}-1}) = L_a(v_3 + c_3) \\ (v_1 + v_2 + v_3)^{2^{e_4}-1} = y + k \end{cases}. \quad (19)$$

Let $v = v_1 + v_2 + v_3$, $c = c_1 + c_2 + c_3$, then Equation (19) can be transformed into the following form by adding the first three equations

$$\begin{cases} L_{\alpha_1}(k^{2^{e_1}-1}) + L_{\alpha_2}(k^{2^{e_2}-1}) + L_{\alpha_3}(k^{2^{e_3}-1}) + L_a(c) = L_a(v) \\ v^{2^{e_4}-1} = y + k \end{cases}. \quad (20)$$

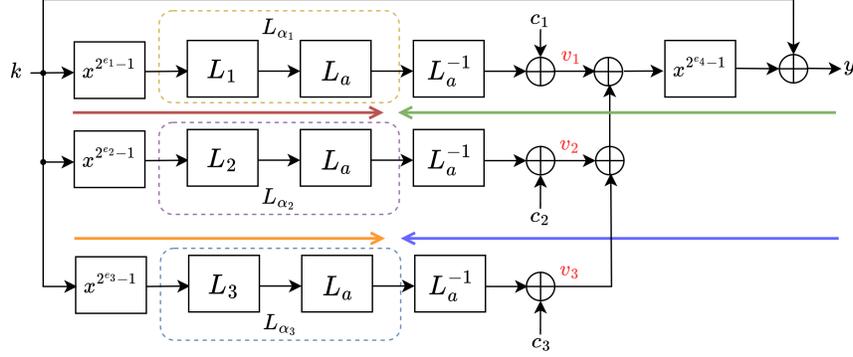

Fig. 7: MITM modeling for AIM-V

Let

$$L_a(x) = \sum_{i=0}^{n-1} a_i x^{2^i}, \quad L_1(x) = \sum_{j=0}^{n-1} d_{1,j} x^{2^j}, \quad L_2(x) = \sum_{j=0}^{n-1} d_{2,j} x^{2^j}, \quad L_3(x) = \sum_{j=0}^{n-1} d_{3,j} x^{2^j}.$$

If we expect that

$$\deg(L_a(x)) \leq 2^l, \deg(L_{\alpha_1}(x)) \leq 2^\gamma, \deg(L_{\alpha_2}(x)) \leq 2^\lambda, \deg(L_{\alpha_3}(x)) \leq 2^\tau$$

for some integers $0 \leq l, \gamma, \lambda, \tau \leq n-1$, then we can obtain the following system of linear equations:

$$\left\{ \begin{array}{l} a_i = 0 \text{ for } l+1 \leq i \leq n-1 \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t_1 \pmod n}} a_i d_{1,j}^{2^i} = 0 \text{ for } \gamma+1 \leq t_1 \leq n-1 \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t_2 \pmod n}} a_i d_{2,j}^{2^i} = 0 \text{ for } \lambda+1 \leq t_2 \leq n-1 \\ \sum_{\substack{0 \leq i, j \leq n-1 \\ i+j \equiv t_3 \pmod n}} a_i d_{3,j}^{2^i} = 0 \text{ for } \tau+1 \leq t_3 \leq n-1 \end{array} \right. \quad (21)$$

Similarly, to ensure that the system of Equation (21) has a non-zero solution, the condition $l + \gamma + \lambda + \tau + 4 > 3n$ should be satisfied. Employing the substitution $v^{2^{e_4}-1} = y + k$ to $L_a(v) = \sum_{i=0}^l a_i v^{2^i}$. For each $e_4 \leq i \leq l$, the term v^{2^i} will be substituted as

$$v^{2^i} = (v^{2^{e_4}-1})^{s_i} v^{r_i} = (y+k)^{s_i} v^{r_i}, \quad r_i < 2^{e_4} - 1 \text{ and } s_i < 2^{l-e_4+1}.$$

Denote the substituted $L_a(v)$ as $h(v, k)$, we have $\deg_k(h) \leq 2^{l-e_4+1}$ and $\deg_v(h) < 2^{e_4} - 1$. Let

$$\begin{cases} f(k, v) := L_{\alpha_1}(k^{2^{e_1}-1}) + L_{\alpha_2}(k^{2^{e_2}-1}) + L_{\alpha_3}(k^{2^{e_3}-1}) + L_a(c) + h(v, k) = 0 \\ g(k, v) := v^{2^{e_4}-1} + y + k = 0 \end{cases}, \quad (22)$$

where $\deg_k(f)$ is bounded by

$$D := \deg_k(f) \leq \max((2^{e_1} - 1)2^\gamma, (2^{e_2} - 1)2^\lambda, (2^{e_3} - 1)2^\tau, 2^{l-e_4+1}).$$

In our setting, the Sylvester determinant associated with $R(f, g, v)$ has size at most $(2^{e_4+1} - 3) \times (2^{e_4+1} - 3)$, each entry in the first $2^{e_4} - 2$ rows contains the variable k with degree D , while each entry in the remaining $2^{e_4} - 1$ rows contains k with degree 1. Similar to the case of AIM-I/III, we can further reduce the determinant size to $(2^{e_4} - 1) \times (2^{e_4} - 1)$, with each entry of the determinant has degree at most $D + 1$. Thus, the complexity of this step can be estimated as

$$\mathcal{O}\left((D + 1)(\log(D + 1))^2 (2^{e_4} - 1)^\omega\right).$$

Next, we aim to select optimal values for l , γ , λ , and τ to minimize D . This involves balancing $(2^{e_1} - 1)2^\gamma$, $(2^{e_2} - 1)2^\lambda$, $(2^{e_3} - 1)2^\tau$, and 2^{l-e_4+1} as close as possible under the condition $l + \gamma + \lambda + \tau + 4 > 3n$. Using the same deduction process as before, let $\beta = \lceil (3n - 3 + e_1 + e_2 + e_3 - e_4)/4 \rceil$, we start to choose $l = \beta + e_4 - 1$, $\tau = \beta - e_3$, $\lambda = \beta - e_2$, and $\gamma = \beta - e_1$. Let $G(k) = R(f, g, v)$, then the degree d of $G(k)$ is bounded by

$$\begin{aligned} d &\leq D(2^{e_4} - 2) + 2^{e_4} - 1 \\ &\leq 2^{\lceil (3n-3+e_1+e_2+e_3-e_4)/4 \rceil} \cdot (2^{e_4} - 2) + 2^{e_4} - 1. \end{aligned}$$

The overall time complexity of our attack on AIM-V can be estimated as

$$\mathcal{O}\left((D + 1) \log((D + 1))^2 (2^{e_4} - 1)^\omega + d \log d (\log d + \log q \log \log d)\right).$$

Experimental Verification. For AIM-I and AIM-III, we randomly generated two linearized permutation polynomials, L_1 and L_2 , with all non-zero coefficients. Starting with the parameters $l = \beta + e_3 - 1$, $\gamma = \beta - e_1$, and $\lambda = \beta - e_2$, we go to find low-degree linearized permutation polynomials L_a, L_{α_1} , and L_{α_2} such that $L_1 = L_{\alpha_1} \cdot L_a^{-1}$ and $L_2 = L_{\alpha_2} \cdot L_a^{-1}$. We finally got concrete linearized permutation polynomials L_a, L_{α_1} , and L_{α_2} for AIM-I/III with degrees $2^{97}/2^{143}$, $2^{91}/2^{132}$, and $2^{67}/2^{108}$, respectively. For AIM-V, we randomly generated three linearized permutation polynomials L_1, L_2 , and L_3 with all non-zero coefficients. We found concrete linearized permutation polynomials with $\deg(L_a) = 2^{210}$, $\deg(L_{\alpha_1}) = 2^{204}$, $\deg(L_{\alpha_2}) = 2^{154}$, and $\deg(L_{\alpha_3}) = 2^{200}$ such that $L_1 = L_{\alpha_1} \cdot L_a^{-1}$, $L_2 = L_{\alpha_2} \cdot L_a^{-1}$, and $L_3 = L_{\alpha_3} \cdot L_a^{-1}$. The time complexities of our attacks are shown in Table 6. Furthermore, we also verified the correctness of our novel attack on all AIM variants over small finite fields (e.g., $\mathbb{F}_{2^{18}}$).

Table 6: Time complexities of our attacks on AIM

Scheme	n	m	l	γ	λ	τ	T	T_{bit}	T_{enc}
AIM-I	128	3	2^{97}	2^{91}	2^{67}	-	$2^{121.0}$	$2^{135.0}$	$2^{114.0}$
AIM-III	192	3	2^{143}	2^{132}	2^{108}	-	$2^{170.8}$	$2^{185.9}$	$2^{163.2}$
AIM-V	256	4	2^{210}	2^{204}	2^{154}	2^{200}	$2^{236.3}$	$2^{252.3}$	$2^{228.3}$

5 Conclusions and Discussions

In this paper, we propose a novel algebraic attack over \mathbb{F}_{2^n} on AO primitives and apply them to RAIN and AIM. The main idea of our attack is to decompose the linearized polynomials with high degrees of the linear layers into low-degree polynomials, such that we can build low-degree equations. To further simplify the equation system, we additionally combine with the meet-in-the-middle modeling, guess-and-determine technique, and resultant, either to reduce the degrees of equations or eliminate variables. All the variants of the 2-round RAIN and full AIM are broken under our attacks.

For future work, it is worth exploring whether our attacks can be combined with other cryptanalysis techniques for AO primitives. Besides, extending the attack to AIM2 [29] would also be interesting. Our attack can also provide some insights for the design of AO primitives. For example, we suggest using two or more linear layers that cannot be merged into one equivalent linear layer when designing AO primitives to resist our attacks.
